THEN AND NOW: A BRIEF HISTORY OF SINGLE BOARD COMPUTERS

The term SBC or single board computer has been around for many years and has meant different things to different people.

BEAGLEBOARD
ELEMENT14.COM/BEAGLEBONE
The element-i BeagleBone Black is a full featured, internet enabled development platform that utilizes the low cost Sitara AM3358 ARM Cortex-A8 processor from Texas Instruments and runs a variety of OS.

ATMEL XPLAINED
ELEMENT14.COM/SAMA5D3
Fast prototyping and evaluation platform based on the SAMA5D3 ARM Cortex-A5. Powerful Atmel’s SAMA5D36 Cortex-A5 MPU, 2GBit DDR2 RAM, 2Gbit Flash, Dual Ethernet (GMAC + EMAC), Arduino® R3-compatible header and LCD connector.

DYNA-MICRO
ELEMENT14.COM/MD-2.HTML
The first true single-board computer, called the “dyna-micro” was based on the Intel C8080A, and also used Intel’s first EPROM, the C1702A. The dyna-micro was re-branded by TAI instruments of Derby, CT in 1976 as the MMD-1 (Mini-Micro Designer 1).

RASPBERRY PI
ELEMENT14.COM/RASPBERRYPI
The idea behind a tiny and affordable computer for kids came in 2006, when Eben Upton, Rob Mullins, Jack Lang and Alan Mycroft, based at the University of Cambridge’s Computer Laboratory, became concerned about the year-on-year decline in the numbers and skills levels of the A-Level students applying to read Computer Science.

In its truest sense, an SBC has referred to a single PC board with the processor, memory and some type of I/O that allowed it to function as a computer – an example of the mid-70s “dyna-micro” was one of the first true single board computers. This differs from a traditional mass produced motherboard in that the early mass market motherboards had expansion slots for many of the key additional peripherals like audio, video and network cards. Today, most consumer motherboards would be considered SBCs as most of the necessary functionality exists on a single motherboard, with the added bonus of being able to upgrade the existing functionality through the use of add-on cards. This is an abbreviated version of the rise of the modern PC.

As stated previously, the term SBC generally refers to a microprocessor based board. But, just as in previous years, semiconductor manufacturers have often supplemented the launch of new products, especially microcontrollers, with development kits or demo boards that engineers could use to test out their newest silicon. These kits were generally used by professional engineers to test out the silicon for their next design. Once the necessary functionality of the microcontroller was confirmed, the designer went into laying out their own board to test out their proof of concept design.

In order to understand the rise of today’s SBCs, we need only look back 10 years ago in Ivrea Italy where a team of designers were looking to develop a lost cost, easy to use microcontroller based development kit that allowed people of all skill levels to make use of modern microcontrollers in their projects. This marked the beginning of the Arduino™ platform. The rapid market acceptance of this prototyping platform paved the way for a new breed of designers entering into the electronics market. Today they are called DIYers, hobbyists and makers among other titles. As the microcontroller based Arduino™ market continued to grow, the cost of microprocessors and SOCs continued to drop dramatically thanks to the success of commercial processor platforms that integrated increasingly more functionality in a single package.

One of the next major developments in the rise of the modern SBC was on July 28, 2008 with the birth of the non-profit BeagleBoard.org. BeagleBoard.org was formed to bring modern microprocessors development into the hands of engineers and designers through a low cost, open source community supported development platform known as the BeagleBoard.

With the Arduino™ and BeagleBone platforms in place and continuing to evolve in the hands of designers, developers and hobbyists, the world was about to experience one of the largest disruptions in both the consumer and industrial computing space – the introduction of the Raspberry Pi.

In 2006, a group based in the University of Cambridge’s Computer Laboratory, decided to address the need for a low cost computing platform that would allow kids to learn how to program without the need for a full-fledged home computer. The result was a $35 single board computer named Raspberry Pi. While initially designed as a tool for students to learn programming, the Raspberry Pi was adopted by makers, designers, students and even professional engineers and helped to launch the current boom in interest in SBCs.

Types of SBCs

While SBCs can be used for most any purpose, many have originally been designed for a specific purpose or application. A perfect example of this is the Raspberry Pi which was developed as an educational tool to help encourage and strengthen students programming skills. The BeagleBoard and BeagleBone were also developed to help educate and promote the benefits and usage of open source hardware and software in embedded computing.

Numerous other SBCs have been developed in the past few years including Atmel’s SAMA5D3 Xplained, which was designed for rapid prototyping development, and the RPiTBoard which focuses on Android development to enable the development of the Internet of Things. Other well-known boards include the PandaBoard, OlinuXino, as well as a whole host of Allwinner ARM SoC based SBCs.

Present Day SBCs

Today, SBCs can be grouped into two main categories – proprietary and open source. Proprietary SBCs are generally designed for use in end applications or as a reference to be evaluated. They are often industrialized designs that have gone through the same type of testing that an end product requires and are often integrated into end product designs or installed in a rack mount configuration. Open source SBCs on the other hand offer users access to both the hardware design and layout as well as access to the source code used on the board. This is ideal for all users as they can easily understand how the software and hardware operates and adopt the design to meet their end designs requirements or simply learn how a piece of hardware or software works.

The long term success of an SBC, like most other products, relies heavily on the performance/price ratio. But what also weighs in just as heavily is the amount of available support for a particular board or range of boards. While some SBCs rely on a dedicated supplier or secondary support entity, most of the open source SBCs are supported through a community of developers. These communities strengthen the boards proposition by providing software updates from individuals as well as projects that showcase the boards features as well as the many accessories that are often available to expand the boards functionality.

The Future of SBCs
Many of today’s SBCs have become so powerful that they are beginning to have the capability of modern day PCs and tablets. This trend will continue as more powerful processors make their way into the embedded computing market as ever-increasing performance/price ratios rise, as well as additional manufacturers enter into this “Wild West” frontier of supporting open source hardware and software for both DIYers and professionals alike.

An additional trend we will continue to see is the availability of more accessories or add-on boards to be added to current SBC platforms, allowing users more options to control and have access to the outside world. This will benefit both DIYers and professionals alike. DIYers that come from a programming background will have increased access to the analog electronics that are required to interface with the outside world. Professional engineers on the other hand can take these accessories and quickly add additional needed functionality to their SBCs to develop working prototypes for projects currently on-hand.

Lastly, another trend that will most likely continue is the adoption of these SBCs into lower volume end products. Many of today’s SBCs are as close to fully vetted designs as those developed specifically for end product usage. This is due to the fact that open source designs are equivalent to having a continual global design review with multitudes of designers and programmers updating and giving feedback on the boards and their software. Additionally, as the design and testing of these boards is done through high quality design and manufacturing firms like AVID or Embest Technologies, the boards go through the same quality control as any other end product and often come with CE or FCC certifications. And, as the cost of these boards is often well below what an individual or company could produce the board for, entrepreneurs and small companies alike, see these boards as an ideal way to quickly bring designs to market without the overhead needed to develop new hardware, but instead focus on the software innovation that is often a key differentiator in todays end product designs.
